Summary. The article provides the analysis of current situation in freight wagon bogies and provides concepts of modern freight car bogies, namely increasing the strength of bogie side frames, lowering dynamic loads, reducing force impact on the railway, increasing the permissible speed, lowering resistance to motion, developing bogies with rolled steel in construction.

The following results. The max. equivalent stress in the side frame with axle-box line 35% below the classic 18-100 and 50% below with using pre-stress. The authors created safety element of bogie side, bogies type 18-100 with the first stage spring suspension in order to improve safety and reduce the dynamics. Are used the method of applying circuit and picked up a profile based on the rails. Preliminary calculations show a reduction in weight. Are reviewed all the major perspective methods of perfection the bogies for reducing force impact on the railway and increase strength. Prepared stand tests of new freight car bogies.

Key words. Bogie, side frame, primary suspension, stress-strain state.

INTRODUCTION

Three element bogies are the main type of bogies for railway freight wagons in Ukraine and in the world (In Ukraine the main model of bogies is 18-100). According to the research of many scientists, this type of bogies is morally obsolete, does not meet the requirements of speed and force impact on the railway. The situation is aggravated by the fact that there are more than 20 failure a year of bogie side frame on the railways of Ukraine and Russia. Therefore, insufficient strength is also a disadvantage of bogie [1-3].

Modernizations of bogies in our country is mainly due to the increase overhaul life. The issue of increasing the strength and speed, reducing of force impact on the railway is not considered.

Also, in many countries are developing a radically new freight wagon bogie [8-10].

OBJECTIVES AND PROBLEMS

The aim of the article is to develop recommendations and constructive solutions to create the concepts of modern freight car bogies, namely to increase the strength of bogie side frames, to reduce force impact on the railway, to increase the permissible speed by closing the axle-box slots on the bogie side frame, using the pre-stressed state of the frame, safety designs, introduction the first stage of suspension [26].

METHODS AND TECHNICAL SOLUTIONS FOR CONCEPTS OF MODERN BOGIES

According to the analysis of breakdowns bogie side frames 18-100, the most dangerous zone is transition Radius R55. It should be noted, that 60% of broken frames contained casting defects. Therefore improving the quality control will partially solve the problem of breakages. And this diagnosis is a very expensive process. Reduced quality of railways (especially the hump yards) exacerbates the problem [8, 24].

Typical breakdown of bogie side frames 18-100 [5, 7] in transition Radius R55 on the railways of Ukraine and Russia is shown in Fig. 1.

Fig. 1. Typical breakdown of bogie side frames
According to the authors, the reason for the accelerated destruction of the side frames is pouring defects [19] and high values of forces on the hump yards. Max. longitudinal force acting on the outer jaw of side frame is 100 kN [24, 25].

Axle-box lines have been using on the locomotives (for example TEM3 – Fig. 2) The scheme with axle-box lines on the side frames of 18-100 (Fig. 3) [14, 23, 27].

The authors calculated static (Fig. 4) and dynamic (Fig. 5) stress-strain state of the side frames 18-100. The max. equivalent stress in the side frame with axle-box line (Fig. 6) 35% below the classic 18-100. Cross-sectional area of axle-box line is 20 cm².

Statistical characteristics of random energy excitatory forces have the power spectral density of acceleration measured in the tests on the axle-box of bogies frame.

According to the results of dynamic calculations have received rms stress in dangerous points (Fig 5) and power spectral density of stress in dangerous points (Fig 7).

The next step is to create a pre-stress in bogie side frame (Fig. 8). If axle-box line pulls together jaws with the force F, general stress in the stress-strain frame reduces.

The value of maximum stress as a function of force F is shown on Fig. 9.

Another technical solution is safety element (fig. 10). There is a redistribution of stresses because of safety element. This element partially retains the jaw after fracture in R55 of side frame.
The authors have developed and patented more than 10 designs of bogies type 18-100 with the first stage spring suspension (Fig. 11 for example). Positive results of this solutions [20, 21, 22]:
- reducing force impact on the railway
- increasing the permissible speed
- lowering dynamic loads
- lowering resistance to motion [16].

Rolled steel is the best material for load-bearing structures. Many companies are developing bogies with rolled steel in construction. For example «Tatravagonka» has developed 18-100 bogie side frame. It is harder than casting, the difference is 50 kg (Fig. 12).

We used the method of applying circuit and picked up a profile based on the rails (Fig. 13). Preliminary calculations show a reduction in weight. Therefore the selection of a profile for the freight bogie is an urgent task [11, 12].

Perspective methods of perfection the bogies are shown in Table 2.
Now there is a preparation for bench tests with axle-box line (fig. 14) at State Economic and Technological University of Transport, Kyiv, Ukraine. And there is a preparation for computer tests of bogies with the first stage of suspension in software complex «UM».

CONCLUSIONS

1. The article provides the analysis of current situation in freight wagon bogies, generally 18-100 model. According to the research of many scientists, this type of bogies is morally obsolete, does not meet the requirements of speed, force impact on the railway and strength.

2. The authors have developed next solutions:
   - axle-box lines on the side frames of 18-100 (max. equivalent stress in the side frame with axle-box line 35% below the classic 18-100),
   - axle-box lines with pre-stressing (max. equivalent stress in the side frame with axle-box line and pre-stressing 50% below the classic 18-100),
   - safety element (this element partially retains the jaw after fracture in R55 of side frame),
   - bogies 18-100 with the first stage spring suspension (reducing force impact on the railway, increasing the permissible speed, lowering dynamic loads, lowering stress in the sidestand),
   - Bogie with rolled steel in construction of side frames (rolled steel has better mechanical properties).

Annotation. In the article is presented an analysis of the current situation in the field of freight wagon bogies and concepts of modern freight bogies, i.e. increase in the strength of the side frames, reduction of dynamic loads, reduction of the force acting on the railway track, increase in the permissible speed, reduction of the resistance to motion, development of a bogie from rolled steel. The following results are obtained. The maximum equivalent stress in the side frame with a suspension roller is 35% lower than the classical 18-100 and 50% lower with the use of preliminary stress. The authors created an element of safety of the side frame, type 18-100 with the first step of the suspension for improving the safety and reducing the dynamic. At this the method is used to study the force of suspensions for the creation of bogies of freight car on the basis of the rails. Predварительные расчеты показывают снижение веса. Рассматриваются все основные перспективные методы совершенствования тележек для уменьшения силового воздействия на железнодорожный путь и повышения прочности. Идет подготовка стендовых испытаний новых тележек грузовых вагонов.

Ключевые слова. Тележка, боковая рама, первичное рессорное подвешивание, напряженно-деформированное состояние.
